### Video 9: Recap: Performing ETL Using NiFi (01:58)

It is now your turn to do ETL. When it comes to ETL, the pattern of extract, transform, and load, a lot of times these are built by hand. Big brittle pipelines that have a lot of challenges as time goes by or as scale increases. Now, when it comes to the patterns that we saw, we took a look at one specific platform, we looked at NiFi, and we used as a source, a simple MySQL database. So, now it's your turn to get some comfort and practice some of these building blocks. So, if you have not done so already, go ahead and recreate the steps that we took in coming up with a solution that could extract, could transform, and load into a viewer inside of the platform.

Now, once you've replicated the work, you could go ahead and change your source quite a bit. You could do different tables, different databases, you could also even replace your database. You'd have to go through the process of uploading the right drivers and to be able to connect to that. Now, when it comes to the platform itself and the steps that we took, we created a very simple processor that was pulling in data, and that was connecting to a follow-on processor. We took a look at the queue of data, the flow files, and how we could capture, load, and view the information that was being pulled.

Now, you could create as many more processors as you want, you could push your data in any direction that you like, but you can see there the core pattern that was illustrated. So, once again, now it is your turn, go ahead and recreate the work originally, to make sure that everything works as you think it should. And then from there on, experiment as much as you like.
