Video 1: Introduction (01:52)

Data engineers move and process data. Now that sounds simple, doesn't it? However, it is one of the most taxing and demanding functions when it comes to the amount of things that need to be done. If you think about the cycle at a high level, you're looking at collection, storage, processing, and consumption of that. That, again, doesn't sound that bad. However, if you were to look simply at collection, you'd look at this data and you'd find out that there's quite a different amount of data that can be collected. You could look at web applications, you could look at mobile apps, you could look at desktops. There's also monitoring and logging, which on its own is a big enough challenge.

There's also IoT, a tremendous volume of information that's coming off from the field, the field intelligence. Now, all of these come in different shapes and different sizes, and then they need to be stored. Now, there's a lot of variety when it comes to the type of storages that you may want to do based on the type and the frequency and the volume, and the variety of the data that you're getting. Now you're stuck with extract, transform, and load. This is a big part of how do you make your data useful. Now when it comes to that, we're going to be looking here at some of the platforms that help us with that.

As usual, we will look at an open source platform that is free of charge to use. There's no licenses that need to be paid for it, but we will go through that extract, transform, and load cycle. Now we will do it as well while building containers. And in this case, we're going to be looking at a richer use of those containers. We will be building some networks that will accompany those containers as well. So, now let's go ahead and get started.
