Video 5: Installing NiFi in a Container (03:23)

Let's create the containers for our system. As you can see here, I'm starting with a blank slate, I have no containers running and I'm going to be doing the installations one-by-one. The very first step is to create a network, this is going to be a network for the two additional containers that we're going to be creating. The first one will be a database server, my SQL, MySQL, and then the second one is going to be NiFi. So, let's create that network now. I will give the network the name of netabel for network able.

So, let's go ahead and create that. And as you can see there, we have created the network. Next, let's create the container for NiFi. And as you can see here, the command from the command, I'm going to be calling it nifiabel. I'm going to be running it on port 8080, mapping onto the host on 8080 as well. I have a note there saying watch out for port conflicts. This is a frequently used port, so if you're already using it, you're going to get a conflict, the collision there. The network I am referencing, the network that we just created, network able netabel. I'm going to run this detached, then you can see there the image that I'm going to be using. So, let's go ahead and create the container. So, as you saw there, the image for NiFi is quite large, so if you're in a slow connection, it's going to take a while. Now, that we have installed or created the container, we can go ahead and navigate to the following, which will be localhost. Then the port is 8080, then NiFi and we can take a look at the user interface.

Now, I've done this simply to confirm that the installation was successful and that we can reach it through this port. Now, we'll go back and install the database. As mentioned, we're going to be using MySQL and as you can see there, I'm going to be using in the command line. I'm going to be using the usual port 3306. I'm going to be calling it mysqlabel. I'm also going to be passing in a password, as you can see, I will be adding it to the network. It'll run detach and you can see there the version that we're going to be creating. So, let's go ahead and paste that command and you can see there the same parameters that I had on the slide.

I'm going to go ahead and return and install MySQL. So, at this point we have created a network, we then add it to that network, NiFi, then we add it to that network, MySQL. Now let's go ahead

and take a look at the dashboard and confirm that those containers are running. So, as you can see here, we have both of those containers, we have NiFi and MySQL up and running. You can see the port that they're in and that they're nice and green and healthy.
