Video 6: Creating and Initializing a Database in a Container (02:00)

Now that we have a database server, let's go ahead and create a database. We're going to create a database called 'Education', and inside of it we will create a table called 'Students'. We'll start off here with some sample data simply to know if we've been successful when we try to read it. So, let's go ahead and move to the workbench. Let's go ahead and connect. Enter the password and as you can see there we are on a clean database. I'm going to go ahead and remove the log for a second and I'll paste a script block.

As you can see there, the very first few lines are creating a database, checking for it, and then if it doesn't exist, it creates it. Then it sets that database to be used. Following that, we will create a table called 'Students.' This table will have three fields, email, name, and city. And after that, that last line is simply inserting some data into this new database and into this new table. So, let's go ahead and run that. And as you can see there, that was successful. And now, let's go ahead and I'm going to go ahead and remove this, and I'll enter here using that database, "use education."

Then I'm going to go ahead and write a query. And I'll here simply enter 'select * from students,' simply to test to see if that is working. So, I'm going to go ahead and run that now. And as you can see there, we have been successful. We got back a row of content, which is what we had added initially.
